

By Royal R. Rife

We have proven precisely that cancer is a virus or the pathogenic portion of chemical constituents that produces the disease. In 8 out of 10 cases we can produce the symptoms of the disease in the experimental animals chemically without any bacteria.

I have in this file over 20,000 cancer tissue section slides. They do not amount to much as far as the virus of cancer is concerned. They show something, but they do not show the virus of cancer. Later I did find it. I produced it with a virus which I isolated from an un ulcerated human breast mass. thru this particular technique of ionization and oxidation and special "K" media that Dr. Kendall developed at Northwestern University. We can take any bacteria and plant it on this media and then after 24 to 36 hours the bacteria is in what we call a transitional state. In the transitional state, it sheds the virus. The virus will produce cancer.

It is an impossibility to stain these filterable forms. Over a period of many years I'd developed a very excellent technique of staining, but I've found nothing.

When I first started work on this research, way back in 1921 and 1922, it was my presumption that when the causitive agent of malignancy would be found, it would be found to be caused by a micro-organism; and not unlikely a so called non-pathogenic micro-organism which we have with us at all times.
